Problem 1

We have that the 4d orbitals have 1 radial node and 2 angular nodes, the possible quantum states are: $(4,2,-2), (4,2,-1), (4,2,0), (4,2,1), (4,2,2)$. For the 5f orbitals, the possible quantum states are $(5,3,-3), (5,3,-2), (5,3,-1), (5,3,0), (5,3,1), (5,3,2), (5,3,3)$. The 5f Orbitals have 3 angular and 1 radial nodes.

Problem 2

(a)

We have that the 5dxy orbital has 2 radial nodes, and 2 angular node planes, one along the xz plane and one along the zy plane. See the figure below for the sketch of the 5dxy orbital.

We have that the angular nodes occur when

$$40 - 14\sigma + \sigma^2 = 0$$

We have that this occurs where $\sigma = 4$ and $\sigma = 10$. Since $\sigma = \frac{2Zr}{na_0}$, we have that the corresponding radii from the origin is

$$r = \frac{na_0\sigma}{2Z}$$

Thus we have that the radii from the origin where the angular nodes occur are $r = \boxed{13.229\text{\AA}}$ and $\boxed{5.291\text{\AA}}$.

(b)

We have that the average radius is given by

$$r = \frac{5^2 a_0}{Z} \left(1 + \frac{1}{2} \left(1 - \frac{6}{25} \right) \right) = \boxed{18.256\text{\AA}}$$

Problem 3

(a)

We have that the radial probability function is given by

$$P(r) = 4r^2 \left(\frac{1}{a_0} \right) e^{-\frac{2r}{a_0}} dr$$

Therefore

$$P(a_0) = \frac{4}{a_0} e^{-2} \cdot 10^{-3} a_0 = 4e^{-2} \cdot 10^{-3} = 0.000541$$

(b)

We have that

$$P(1) = 0$$
